

Java Cloud Service Demo Guide: Application Continuity

Description

For Use By	Oracle Sales / Pre-Sales, Consulting, Product Managers, Solution Managers, etc
Internal/External Consumption	Internal
Target Audience	<ul style="list-style-type: none">• Customer / Partner<ul style="list-style-type: none">○ Architects,○ Development Leads
Demo Duration (Approximate)	Approximately 15 minutes.
Background Knowledge Required/Suggested	<ul style="list-style-type: none">• Maven• WLS architecture• WLST• Git
Related Materials	<ul style="list-style-type: none">• Oracle Public Cloud Services<ul style="list-style-type: none">○ Java Cloud Services○ Database Cloud Services• Git or Downloaded Sources• Java Development Kit 1.8+• Apache Maven 3.2.5+

Feature Overview

Application Continuity is a feature that enables the replay, in a non-disruptive and rapid manner, of a request against the database after a recoverable error that makes the database session unavailable.

The request can contain transactional and non-transactional work. After a successful replay, the application can continue where that database session left off, instead of having users left in doubt not knowing what happened to their funds transfers, flight bookings, and so on, and avoiding the need to reboot mid-tier machines to recover from logon storms.

With Application Continuity, the end user experience is improved by masking many outages, planned and unplanned, without the application developer needing to attempt to recover the request.

Without Application Continuity, it can be almost impossible for an application to mask outages in a safe way.

Demo Overview

Two scenarios will be demonstrated:

In the first case, we would be using the old JDBC driver and thus when a transaction fails midway due to the abrupt killing of a database session – the transaction fails / remains incomplete and thus data is not written to the database tables.

In the second case, we would be using the new 12C JDBC drivers and thus when a transaction fails midway due to the abrupt killing of the database session, the transaction still goes through.

Requirements / Prerequisites

- Windows or Linux operating system
- Computer with 2 GB RAM
- Java Development Kit 1.8+
- Apache Maven 3.2.5
- Git
- A web browser is required for working with Oracle Cloud services. These are the minimum requirements:
 - Microsoft Internet Explorer 9 or 10 with Browser Mode and Document Mode set to IE9 or IE10
 - Mozilla Firefox 24 and later
 - Google Chrome 29 and later
 - Apple Safari 6 and later
- Roles and Credentials - You must have the following roles and credentials:
 - Roles and privileges described in Oracle Cloud User Roles and Privileges in Getting Started with Oracle Cloud
 - Log-in credentials for creating Oracle Java Cloud Service instances and for working with the associated database and storage services.
 - Java Administrator role (This role lets you create Oracle Java Cloud Service instances.)
 - For more information, see About Oracle Java Cloud Service Roles and User Accounts in Using Oracle Java Cloud Service.

Tips

- Use FireFox for the demos.

Demo Steps

Setup & Dependencies

1. Install Java Development Kit and Apache Maven
The SSH connection requires advanced Unlimited Strength Java Cryptography Extension which is not enabled by default due to import control restrictions of some countries. Please [download the necessary extension policy](#) files (local_policy.jar, US_export_policy.jar) and copy it to your <java-home>/lib/security
For detailed information see the instructions attached to policy files.
2. Follow the steps outlined in [WInS - Demo Guides - Setup – Clone Git repository](#) to get the necessary sources ready.
3. To create necessary (JCS and DBCS) environment follow the [WInS - Demo Guides - JCS Setup.pdf](#)
4. Environment variables and directories
 - a. This document will refer to the local clone of WInS remote repository as **WINS_SOURCE_REPOSITORY**. Every steps where it is used replace to your location.
 - b. Set JAVA_HOME to point your jdk location. Example:
Windows: set JAVA_HOME=c:\jdk1.8.0_31
Linux: export JAVA_HOME=/usr/java/jdk1.8.0_31
 - c. Add Apache Maven to your PATH variable. In this case it is easier to execute maven. Example:
Windows: set PATH=%PATH%;c:\apache-maven-3.2.5\bin
Linux: export PATH=\$PATH:/usr/apache-maven-3.2.5/bin

Executing the Side by Side Deployment demo

The demo environment preparation does not require manual access, configuration to the Java and Database Cloud Service. All changes will be done by Maven installation. It is important to use clean JCS environment otherwise error can happen during the execution.

- 1) First get the IP address of your Java Cloud Service instance's Administration server and Database Cloud Server instance.

To get JCS information run the following maven command in WINS_SOURCE_REPOSITORY\cloud.demos directory:

```
mvn install -DexecuteCloudUtil -Dgoal=jcs-get-instance-details
```

The following result will contain the necessary address:

```

C:\Windows\System32\cmd.exe
c:\Java\git_repos\weblogic-innovation-seminars.cloud\cloud.demos>mvn install -DexecuteCloudUtil -Dgoal=jcs-get-instance-details

```

Or this information is also available on the Database Cloud Service console as in case of Java Cloud Service. Click on

the desired DBCS instance and you can see the IP address.

The screenshot shows the Oracle Cloud My Services dashboard for the instance **winstestDB2**. The top navigation bar includes the Oracle logo, "CLOUD My Services", and links to Dashboard, Users, and Notifications. The main content area has a left sidebar with "Overview" and "Administration" sections. The "Overview" section shows a summary of the instance: 1 Node, 1 OCPU, 7.5 GB Memory, and 101 GB Storage. The "Administration" section has a link to "View Patch Information". The main content area displays the instance details for **winstestDB2**, including its Public IP address (129.191.1.134), SQL *Net Port (1521), SID (ORCL), Container Name (ORCL), and PDB Name (PDB1). Below this, there is an "Activity" section and an "Additional Information" section with details such as Edition (Enterprise Edition), Service Level (Oracle Database Cloud Service), Subscription Type (Monthly), Created On (Oct 27, 2015 6:09:59 PM UTC), Created By (peter.nagy@oracle.com), Identity Domain (jcsdemo027), Connect String (winstestDB2:1521/PDB1.jcsdemo027.oraclecloud.internal), Backup Destination (Both Cloud Storage and Local Storage), and Cloud Storage Container (Storage-jcsdemo027/wins_container_2).

- 2) Once we have the JCS and DBCS instance's public IP addresses change directory to `WINS_SOURCE_REPOSITORY\cloud.demos\application-continuity`
 Execute the maven build with the following options:
`mvn install -DprepareApplicationContinuity -Djcs.ip=129.191.0.44 -Ddbcs.ip=129.191.1.134`
 Don't forget to change the IP addresses according to your environment.
 The process will copy the scripts and application archive to the JCS and/or DBCS instance. Then execute the setup scripts. The result output should be the following:

```
C:\Windows\System32\cmd.exe - mvn install -DprepareApplicationContinuity -Djcs.ip=129.191.0.44 -Ddbcs.ip=129.191.1.134
ip=129.191.1.134

```

3) Testing the environment for the Application Continuity demo:

- Go to the browser and type the URL: https://<AdminServer_VM_IP_Address>:7002/otrade/setup.jsp
- Enter the following:

- Listener Addresses: <DBCS_INSTANCE_NAME>:1521

For example **winstestDB2** in the case below:

 winstestDB2 Public IP: 129.191.1.134	SQL *Net Port: 1521 SID: ORCL Container Name: ORCL PDB Name: PDB1	OCPUs: 1 Memory: 7.5 GB Storage: 101 GB
--	--	---

- ii. Username: system
- iii. Password: password specified during creation of DBCS and in environment.properties
Important! If the password or username contains non-alphanumeric characters then during the submit request can be corrupted. Please convert any special character to URLEncoded format. For example the # character encoded format is %23.
- iv. DB Name: AC.<CLOUD_IDENTITY_DOMAIN>.oraclecloud.internal
You can check your full DBCS network postfix (including identity domain) on the console. For example using the information below we can get the following name:
AC.jcsdemo027.oraclecloud.internal

Additional Information

Edition:	Enterprise Edition
Service Level:	Oracle Database Cloud Service
Subscription Type:	Monthly
Created On:	Oct 27, 2015 6:09:59 PM UTC
Created By:	peter.nagy@oracle.com
Identity Domain:	jcsdemo027
Connect String:	winstestDB2:1521/PDB1 AC.jcsdemo027.oraclecloud.internal
Backup Destination:	Both Cloud Storage and Local Storage
Cloud Storage Container:	Storage-jcsdemo027/wins_container_2

The AC service created by the setup script. The demo requires additional service because the application continuity settings are different comparing to the default (PDB1) service.

For more information check the setup sql script in the repository.

- v. Click on “1a. DB Ping” and verify the database connectivity.

← → ↻ <https://129.191.0.44:7002/otrade/setup.jsp>

5) Testing the Application with new data source (supporting JDBC Replay)

- Open a new tab in the browser and type the following URL:
https://<AdminServer_VM_IP_Address>:7002/otrade/account.jsp
- Enter the following:
 - Datasource: otrade-replay-ds
 - SYS Password: <password specified during creation of DBCS>
- Click on **“Query->Next 2 Records->Kill Session->Next 2 Records”**.

At the first instant, two records will be printed on the screen. At the next step when the session is killed and we try to get the next two records – we do not get an exception in this case. Even though the session had been killed, still due to JDBC Replay and Application Continuity, we are able to retrieve the next two records with the help of the new 12C JDBC driver.

Customer: History:

SYS Password:

Select Replay: Update Replay:

history query for customer1

## When to use

- Introduction
  - In today's environment, application developers are required to deal explicitly with outages of the underlying software, hardware, communications, and storage layers. As a result, application development is complex

and outages are exposed to the end users. For example, some applications warn users not to hit the submit button twice. When the warning is not heeded, users may unintentionally purchase items twice or submit multiple payments for the same invoice.

- Application Continuity (also referred to as Replay) is a general purpose, application-independent infrastructure for GridLink and Generic data sources that enables the recovery of work from an application perspective and masks many system, communication, and hardware failures. The semantics assure that end-user transactions can be executed on time and at-most-once. The only time an end user should see an interruption in service is when the outage is such that there is no point in continuing.
- What happens in the absence of Application Continuity
  - Without Application Continuity, it can be almost impossible for an application to mask outages in a safe way, for reasons that include the following:
    - The state at the client remains at present time, with entered data, returned data, and variables cached.
    - If a commit has been issued, the commit message is not durable.
    - Checking on a lost request is no guarantee that it will not commit after checked.
    - Non-transactional database session state that the application needs to operate is lost.
    - If the request can continue, the database and the database session must be in the right state.
  - Application Continuity, however, does this work for the application developer, thus masking many outages in a safe way.
- How it works
  - Following any outage that is due to a loss of database service, planned or unplanned, Application Continuity rebuilds the database session. Once an outage is identified by Fast Application Notification or a recoverable ORACLE error, the Oracle driver:
    - Establishes a new database session to clear any residual state.
    - If a callback is registered, issues a callback allowing the application to re-establish initial state for that session.
    - Executes the saved history accumulated during the request.
  - The Oracle driver determines the timing of replay calls. Calls may be processed chronologically or using a lazy processing implementation depending on how the application changes the database state. The replay is controlled by the Oracle 12c Database Server. For a replay to be approved, each replayed call must return exactly the same client visible state that was seen and potentially used by the application during the original call execution
- How does Application Continuity help?

- Application Continuity improves developer productivity by attempting to mask outages that can be masked. Note, however, that applications still must include error handling for these cases:
  - Non-recoverable errors, such as invalid input data. (Application Continuity applies only to recoverable errors.)
  - Recoverable errors when replay has encountered one of the [restrictions](#), such as use of concrete classes in the application, or when replay has not been able to restore the client-visible state to that on which the client may have made decisions so far.

## Typical Questions

- How to write recovery code with Transaction Guard
  - Blogged [here](#).
- Ensuring Application Continuity.
  - Documented [here](#).
- More about DBMS\_Service
  - Available [here](#).
  - This should help in understanding the various nuances of the options available during creation of a 'Service'
- Oracle Whitepaper on Oracle WebLogic Server Integration with Oracle Database 12c
  - Available [here](#).
- Oracle Whitepaper on Application Continuity with Oracle Database 12c
  - Available [here](#).
- Oracle Whitepaper on Oracle Database 12c Application Continuity for Java
  - Available [here](#).
- WebLogic Server Blog on 12C Database and WLS - Application Continuity
  - Available [here](#).
- More about Application Continuity
  - Available [here](#).
  - Helps in understanding the working of Application Continuity.
- Limitations with Application Continuity with Database Release 12.1.0.1

- Proxy authentication is not supported. That is, a transaction request will not be replayed and the original `java.sql.SQLRecoverableException` is thrown if an outage occurs.
- DRCP is not supported. That is, a web request will not be replayed and the original `java.sql.SQLRecoverableException` is thrown if an outage occurs.
- Cannot be used with PDB tenant switching using `ALTER SESSION SET CONTAINER`.

## Wrap Up / Conclusion

Introduced in Oracle Database 12c Release 1 (12.1.0.1), Application Continuity strengthens the fault tolerance of systems and applications that use an Oracle database.

This new JDBC Driver is available only with Oracle WebLogic Server 12C and Oracle Database 12C.

The WInS cloud tool makes the provisioning, delete easier and faster. Instead of getting REST client tool and/or clicking through the console wizard the instance creation is much easier and less error proning.

## Troubleshooting

To get more information it is useful to check the server output. It requires [Secure Shell \(ssh\) connection to the JCS](#) instance. After a successful login switch to oracle user:

```
sudo su - oracle
```

and print the tail of the output log:

```
tail -f
```

```
$DOMAIN_HOME/servers/<first_8_character_of_JCS_instance_name>_adminserver/logs/winstEST_adminserve
r.out
```

In the log you can see the following entries which are created by the applications when database connection is necessary:

```
=====DB username: system
=====DB password: Welcome1#
=====DB service: AC.jcsdemo027.oraclecloud.internal
=====Connection url: jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCP) (HOST=winstestDB2) (PORT=1521))) (CONNECT
DATA=(SERVICE_NAME=AC.jcsdemo027.oraclecloud.internal)))
=====Server name: Oracle
=====Server version: Oracle Database 12c Enterprise Edition Release 12.1.0.2.0 - 64bit Production
With the Oracle Label Security option
=====Driver name: Oracle JDBC driver
=====Driver version: 12.1.0.2.0
=====Driver's jar: /u01/app/oracle/middleware/oracle_common/modules/oracle.jdbc.12.1.0/ojdbc7dms.jar
=====Connection url: jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCP) (HOST=winstestDB2) (PORT=1521))) (CONNECT
DATA=(SERVICE_NAME=AC.jcsdemo027.oraclecloud.internal)))
```

Here you can check whether the username and password was submitted successfully in case any of them contains non-alphanumeric characters.

If the preparation or remove script fails check the Weblogic instance through its administration console.
