

Java Cloud Service Demo Guide: Side-by-side deployment

Description

For Use By	Oracle Sales / Pre-Sales, Consulting, Product Managers,
	Solution Managers, etc
Internal/External Consumption	Internal
Target Audience	Customer / Partner
	Architects,
	 Development Leads
Demo Duration (Approximate)	Approximately 10 minutes, plus the time needed for Oracle
	Cloud to provision your service instance. (Provisioning is the
	process of allocating cloud resources for your service
	instance.)
Background Knowledge	Maven
Required/Suggested	WLS architecture
	WLST
	Git
Related Materials	Oracle Public Cloud Services
	 Java Cloud Services
	 Database Cloud Services
	Git or Downloaded Sources
	Java Development Kit 1.8+
	Apache Maven 3.2.5+

Feature Overview

Weblogic Server supports a feature called side-by-side deployment (or versioned deployment). This function is extremely useful when you need to deploy a new version of an application and still keep the old one up and running. So the running instances will still use the current version and all new instances will be able to invoke the new deployed version of the application.

As soon as all the sessions that are using the old version of the application are expired, Weblogic will recognize it and will deactivate the old version. So at this moment only the new deployed version is active and all new sessions will make us of it.

This is often referred to as Production Redeployment too.

Demo Overview

So how does this work?

You could either use shell scripting (WLST or weblogic.deployer) to deploy the application and specify the version number on deployment as one of the parameters or you can use the manifest.mf file. We'll be using the first one.

A viewlet of the same is available <u>here</u> as well.

We would be deploying V1 of an application, using it for some time. Then deploy V2 in Administration mode for the Admin / Developer to verify proper the functionality. Then V2 would be promoted. The sessions which are already logged in will be using the previous version (V1) of the application and the new sessions created will use the new version of application (V2). And once all the sessions that were using V1 are expired, it would finally be deactivated.

Requirements / Prerequisites

- Windows or Linux operating system
- Computer with 2 GB RAM
- Java Development Kit 1.8+
- Apache Maven 3.2.5
- Gif
- A web browser is required for working with Oracle Cloud services. These are the minimum requirements:
 - Microsoft Internet Explorer 9 or 10 with Browser Mode and Document Mode set to IE9 or IE10
 - o Mozilla Firefox 24 and later
 - Google Chrome 29 and later
 - o Apple Safari 6 and later
- Roles and Credentials You must have the following roles and credentials:
 - Roles and privileges described in Oracle Cloud User Roles and Privileges in Getting Started with Oracle Cloud
 - Log-in credentials for creating Oracle Java Cloud Service instances and for working with the associated database and storage services.
 - Java Administrator role (This role lets you create Oracle Java Cloud Service instances.)
 - For more information, see About Oracle Java Cloud Service Roles and User Accounts in Using Oracle Java Cloud Service.
- Existing Database and Java Cloud Services.

Tips

• Use FireFox for the demos.

Demo Steps

Setup & Dependencies

- 1. Install Java Development Kit and Apache Maven
- Install Java Development Kit and Apache Maven
 The SSH connection requires advanced Unlimited Strength Java Cryptography Extension which is not enabled by default due to import control restrictions of some countries. Please <u>download the necessary extension policy</u> files (local_policy.jar, US_export_policy.jar) and copy it to your <java-home>/lib/security
 - For detailed information see the instructions attached to policy files.
- 3. Follow the steps outlined in WInS Demo Guides Setup Clone Git repository to get the necessary sources ready.
- 4. To create necessary (JCS and DBCS) environment follow the WInS Demo Guides JCS Setup.pdf
- 5. Environment variables and directories
 - a. This document will refer to the local clone of WInS remote repository as WINS_SOURCE_REPOSITORY.
 Every steps where it is used replace to your location.

b. Set JAVA_HOME to point your jdk location. Example:

Windows: set JAVA_HOME=c:\jdk1.8.0_31

Linux: export JAVA_HOME=/usr/java/jdk1.8.0_31

c. Add Apache Maven to your PATH variable. In this case it is easier to execute maven. Example:

Windows: set PATH=%PATH%;c:\apache-maven-3.2.5\bin Linux: export PATH=\$PATH:/usr/apache-maven-3.2.5/bin

Executing the Side by Side Deployment demo

- 1) Get the public IP address of your Java Cloud Service Instance Administration Server Java. To obtain this information there are two options.
 - a. Open terminal/command prompt and change directory to WINS_SOURCE_REPOSITORY\cloud.demos
 Execute the maven build with the following options:
 mvn install -Dgoal=jcs-get-instance-details
 The result output will show the IP address:

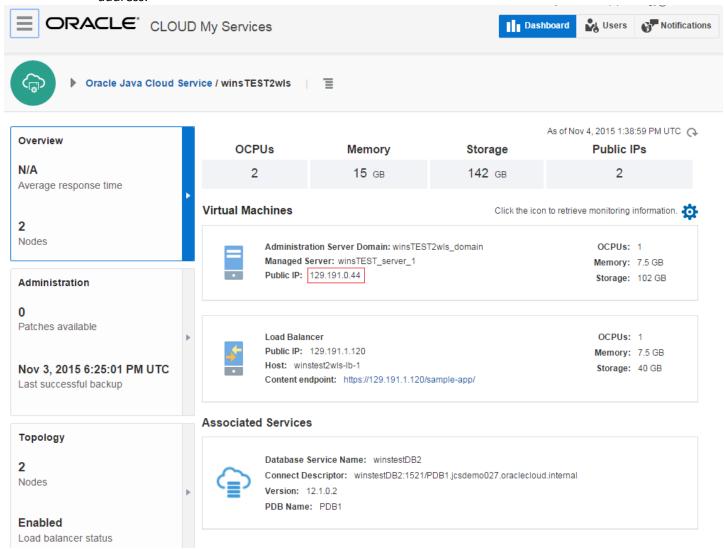

```
a\git.repos\weblogic-innovation-seminars.cloud\cloud.demos\mvn install -DexecuteCloudUtil -Dgoal=jcs-get-instance-details

```

b. Or open the Java Cloud Service Console. Click on the desired JCS instance and you can see the public IP address.

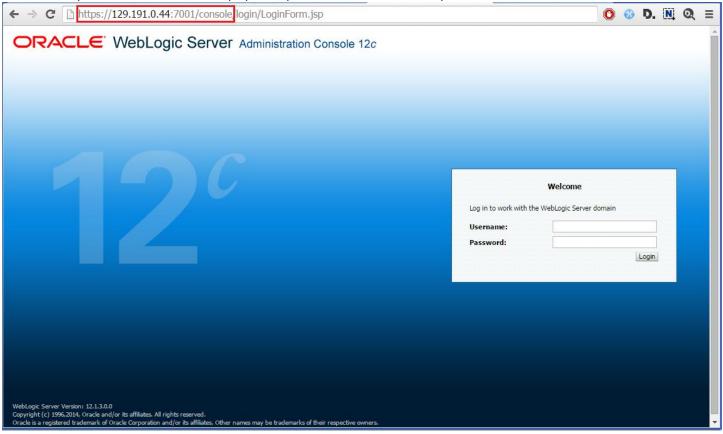

To check the current port availability —which will change below- open the Weblogic Admin Console. Click on the JCS console to open.

Or enter the public IP address with https prefix, port number and console path into a browser.

- 2) Setup and configure Java Cloud Service instance. Run the following maven build in the WINS_SOURCE_REPOSITORY\cloud.demos\side-by-side-deployment directory: mvn install -DprepareSideBySide -Djcs.ip=129.191.1.19
 The preparation includes:
 - Stopping Managed Servers to apply administration port settings
 - o Enable administration port on 7200
 - o Enable Tunneling for Admin server.

```

Important: after the modification you cannot access to the Weblogic Admin Console through the known and preconfigured port 7002. When the administration port is enabled you can access through only that port using ssl connection. So move forward to enable external access to the newly defined administration port which is by default disabled.

3) Now we need to enable a port on the JCS VM – so that external traffic can be channeled to the VM. Login to the Oracle Public Cloud and visit the Oracle Compute Cloud Service home page. From here click on 'Open Service Console'

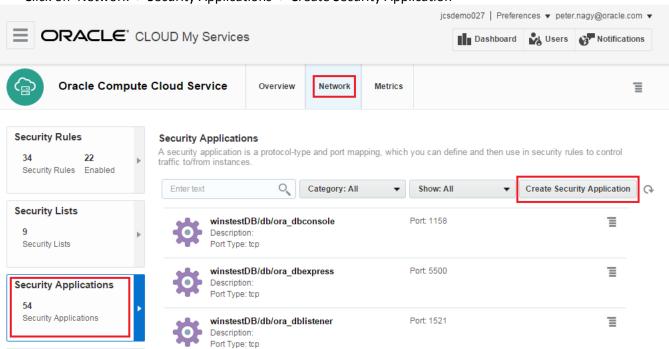

Or click on the console shortcut and select 'Compute Cloud Service'

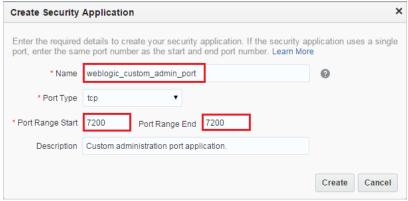

Click on 'Network -> Security Applications -> Create Security Application'

Now create a generic 'Security Application' which can enable top access through port 7200. Define the values as per mentioned in the image below:

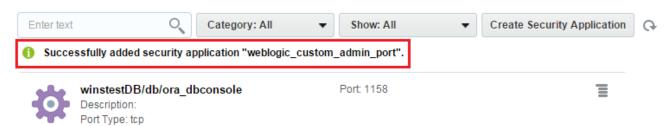

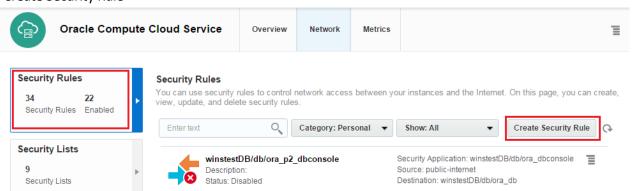

Once the protocol is created – a success message is shown.

Security Applications

A security application is a protocol-type and port mapping, which you can define and then use in security rules to control traffic to/from instances.

Now create the a new rule what will asssign the 'Security Application' to the desired instance. Click on 'Security Rules -> Create Security Rule'

Define the values for the new rule:

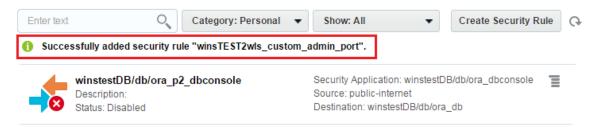

- Name: choose what you want
- Status: Enabled (default)
- Security Application: select the previously created Security Application.
- Source: select Security IP Lists and the predefined public-internet
 Note: Here you can also create specific source address to restrict external access for more security.
- Destination: select the predefined <JCS_INSTANCE>/wls/ora_admin
- Description: choose what you want.

Once the Access Rule is created, a success message is shown.

Security Rules

You can use security rules to control network access between your instances and the Internet. On this page, you can create, view, update, and delete security rules.

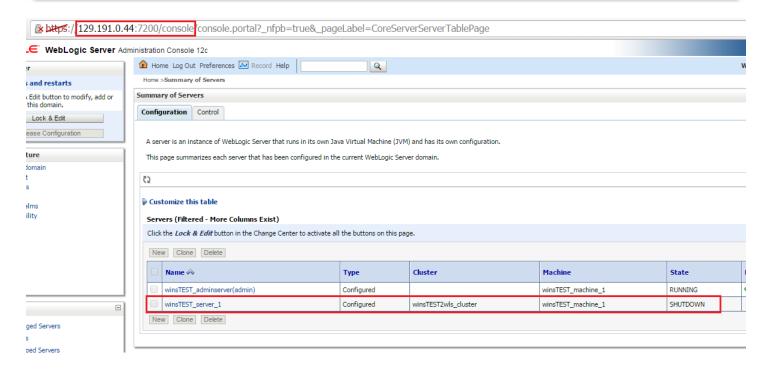

Now check the Weblogic Admin Console access through the new administration port. Don't try to open through JCS console because that will try through the 7002 port. You can check just for sure.

So change the port to 7200 in console url, accept the risks, add the exception and proceed to be able to access the WebLogic Server Admin Console. Optionally you can check the managed server's status. It should be shutdown.

4) Now is the time to deploy the application. Execute the following maven build in the WINS_SOURCE_REPOSITORY\cloud.demos directory:

mvn -DexecuteSh -Djcs.ip=129.191.0.44 -Dsh=Deploy-Aussie_tripper.sh

Note: use your instance's public IP address and don't forget to change the directory one level up. The result should be the following:

```
a\git.repos\weblogic-innovation-seminars.cloud\cloud.demos><mark>nvn -DexecuteSh -Djcs.ip=129.191.8.44 -Dsh=Deploy-Aussie_tripper.sh</mark>

```

Go back to the WebLogic Server admin console and notice that there are 2 versions of the application deployed. And both are in Active state.

▽ X

Launch a different browser and access the Version 2 of the application using the url: <a href="https://<ip">https://<ip address of the JCS VM>:7200/aussie-tripper. Login using the user name password which are used to login to the admin console It can be useful to use a different browser to avoid any caching issues.

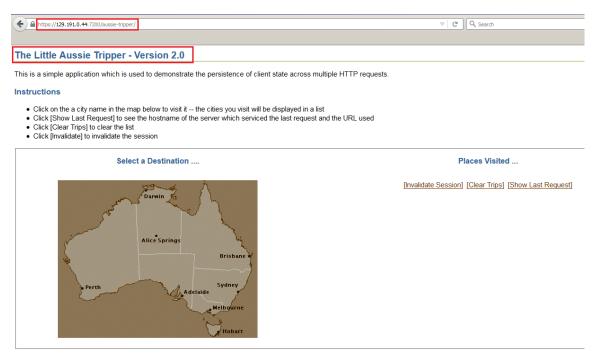

This should bring up the version 2 of the application.

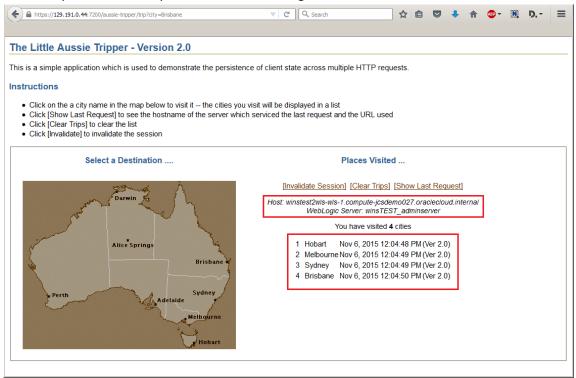

♦ https://129.191.0.44:7200/aussie-tripper/

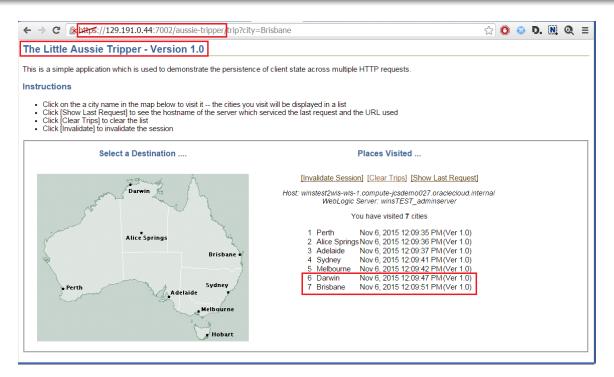

Click on a few places of the map and see that it is being reflected on the screen.

Go back to the other browser, where Version 1 was running and click on some more places on the map. You will notice that the state of the application of Version 1 was alive and more places are being continued to be clicked.

6) Now, you have to promote Version 2 of the application to go into production (change it from admin mode). Execute the following maven build in the WINS_SOURCE_REPOSITORY\cloud.demos directory:

mvn install -DexecuteSh -Djcs.ip=129.191.0.44 -Dsh=Promote-Aussie_tripper_v2.sh

Note: use your instance's public IP address. The result should be the following:

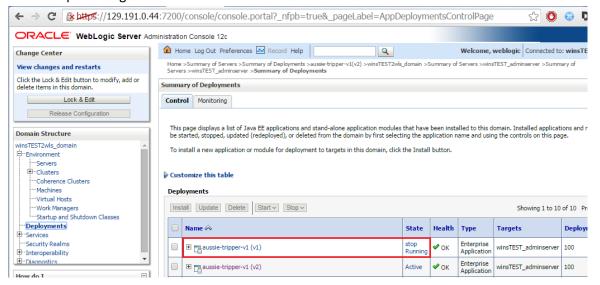

```
ava\git.repos\weblogic-innovation-seminars.cloud\cloud.demos<mark>mvn install -DexecuteSh -Djcs.ip=129.191.0.44 -Dsh=Promote-Aussie_tripper_v2.sh</mark>

```

The application is deployed. Go to the WebLogic Server admin console and refresh the deployments screen.

Version 1 is not in Stop Running state while Version 2 is in Active state.

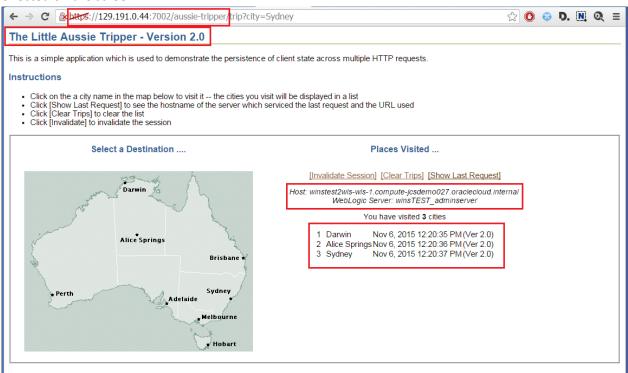

Go the browser where V1 was running and click on 'Invalidate Session'. A message will be shown that the session has ended. Click on the link to access the application again.

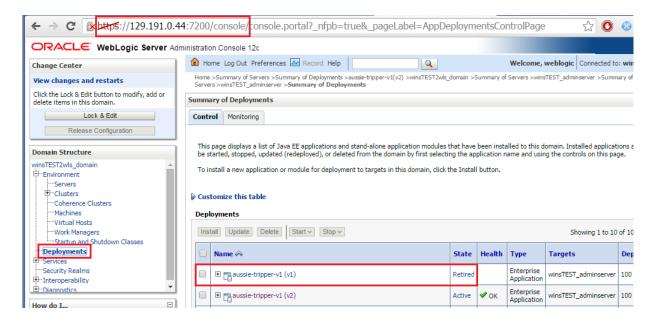

This time when the page loads it is version 2 of the application. You can click on various places on the map and the same will be reflected on the screen.

Close both application's browsers page/tab and login again to WebLogic Server Admin Console. Check out the Deployments page. This time you will notice that the Version 1 of the application is now in 'retired' state while Version 2 is in Active state.

Restore Java Cloud Service Instance

 In order to roll back the changes on JCS execute the following maven build in the WINS_SOURCE_REPOSITORY\cloud.demos directory: mvn install -DexecuteSh -Djcs.ip=129.191.0.44 -Dsh=-Dsh=restoreJCS.sh

Note: use your instance's public IP address. The result should be the following:

Troubleshooting

If the script fails the following steps need to be complete:

- Undeploy all versions of Aussie-tripper application
- Disable Administration port (Domain -> Configuration -> General)
- Disable Tunneling (Adminserver -> Protocol -> General)

Note: once you have apply changes (Disable Administration port) the Admin console will no longer available on port 7200.

Typical Questions

- Side by Side deployment importance and steps
 - Releasing a new version of the product is not an easy task. After finishing development cycles and QA cycles, finally it is time to deploy the new version to the application server. Servers are shut down, the new version of the product is swapped in, and then pray there is no issue once everything comes up. If

you are lucky, only a few issues will show up. However if you are not in luck then you have to roll back the old applications, and it is even more painful than deploying the new version, because sometimes you cannot roll back all of the changes.

- This is when it helps to have multiple versions on the application server and one could switch between each version without interrupting the system.
- Side-by-side application deployment controls the process for deploying new versions of Web-based applications without the need to disrupt service. The new version of an application is deployed alongside existing version WebLogic will gradually migrate the traffic. The older version is automatically un-deployed after all current clients complete their work. The Administrator explicitly un-deploys the older version, or a configured timeout is reached.
- Rolling back the new version is simple: just stop the redeployment process if problems are detected in the newer application version.
- For new applications, administrators can deploy an application in "administration mode," which makes it
 inaccessible to non-admin clients, in order to do sanity checks to ensure that the application is working
 as expected and then open it up to clients.
- List of the features of side-by-side deployment
 - Multiple application versions can coexist
 - Test versions before releasing to users
 - o Roll back to previous versions
 - o Automatic retirement: graceful, timeout, immediate
 - Creates version-aware application artifacts/resources
 - o Reduces hardware, software, maintenance, and support costs

Pre-requisite

- Prerequisite to deploy the application using "Side By Side Deployment" mechanism is that the previously deployed application has to be versioned.
- If previously deployed application is not versioned then the new application cannot be deployed using
 "Side By Side Deployment" mechanism. If attempted, it will throw
 weblogic.management.ManagementException: [Deployer:149081]You cannot deploy application,
 '[Your-App-Name]', with version '[App-Version]'. The application was previously deployed without
 version.

Wrap up / Overview

Sometimes, this is also referred to as Production Redeployment. This enables you to update and redeploy an application in a production environment without stopping the application or otherwise interrupting the application's availability to clients. Production redeployment saves you the trouble of scheduling application downtime, setting up redundant servers to host new application versions, manually managing client access to multiple application versions, and manually retiring older versions of an application.
